UFUNCTION(meta=(DevelopmentOnly))
float NotSoImportantDebugFunc();
```

# 1.2 UENUM()

${f Blueprint Type}$	Enums marked with this attribute, can
	be used from within Blueprints.
Bitflags (Meta)	Enums marked with this attribute, can
	be used as BitMask in UPROPERTYs.
DisplayName (UMETA)	Use this inside of an Enum, to override
	the name displayed inside the Editor.
	See usage below:
//Note that enums must	be declared before any class

```
UENUM(BlueprintType)
enum class ETestEnum {
    FirstEntry UMETA(DisplayName="OtherName"),
    //...
UENUM(meta=(Bitflags))
enum class EMyEnum {
FirstBit,
SecondBit
```

## $1.3 \quad \text{UPARAM}()$

$\mathbf{ref}$	By default, when you pass an reference to a Blueprint	
	callable function, it will appear as an output node	
	in the Editor. Use this attribute, to mark it as an	
	input.	
DisplayName	Use this name to override the name under which the	
	parameter appears in the Blueprint Editor	

```
UFUNCTION(BlueprintCallable)
void MyFunc(UPARAM(ref) TArray<int>* IntArray);
UFUNCTION(BlueprintCallable)
void OtherFunc(UPARAM(DisplayName="Name" float f);
```

# 1.4 UCLASS()

Abstract	An class that is marked as abstract can not be	
	placed or instanced during runtime. This is es-	
	pecially useful for classes, that does not provide	
	functionality on their own and must be inherited	
	and modified for meaningful usage.	
Blueprintable	Classes marked with this attribute can be used as a	
	base class for creating Blueprints. On Default this	
	is deactivated. The attribute is inherited by child	
	classes, use NotBlueprintable on childs to disable	
	this.	
BlueprintType	Classes with this attribute can be used as variable	
	type in Blueprints.	
Placeable	Classes marked as Placable, can be created and	
	placed in a level, UI Scene or Blueprint via the	
	Editor. The flag is inherited by all child classes, use	
	NotPlacable on child to disable this.	

```
UCLASS(Blueprintable)
class MyClass : public UObject {
//Class code ...
```

#### 1.5 UPROPERTY()

Multicast Delegates only. Exposes property
for assigning in Blueprints
Multicast Delegates only. Property property
for calling in Blueprints
This property can be read by blueprints, but
not modified
This property can be read or written from a blueprint
Specifies the category of the property within
the Editor. Supports sub-categories separated by " "
Indicates that this property can be edited via
property windows, archetypes and instances within the Editor
Indicates that this property can be edited by
property windows, but only on archetypes This operator is incompatible with the Visible* specifiers
Indicates that elements of an array can be
modified in Editor, but its size cannot be
changed
Indicates that this property can be edited by
property windows, but only on instances, not
on archetypes
Property is transient: shouldn't be saved.
zero-filled at load time
Indicates that this property is visible in prop-
erty windows, but cannot be edited at all
Indicates that this property is only visible in
property windows for archetypes, and cannot be edited
Indicates that this property is only visible
in property windows for instances, not for
archetypes, and cannot be edited
Moves the property into the Advanced drop-
down in the Details panel within the Editor
Hides the clear and browse button in the editor for this property.
The property can only be edited in Editor if
the specified bool Property is true. Use! to
invert logic (so you can only edit property if
bool is false).
Change the value of this property in the Ed-
itor using a BitMask, which means you can
select the value of each single bits. Use Bit-
Mask to specify a Enum, which entries will
be used to name each bit.
be used to name each bit.  Use this on float or int property, to specify a
Use this on float or int property, to specify a
Use this on float or int property, to specify a
Use this on float or int property, to specify a maximum/minimum, that can be entered for this property in the Editor
Use this on float or int property, to specify a maximum/minimum, that can be entered for

```
UPROPERTY(EditAnywhere, Category="Category|Sub")
bool BoolProperty;
UPROPERTY(BlueprintReadOnly, AdvancedDisplay)
TSubclassOf<UStaticMesh> AdvancedMeshClass;
UPROPERTY(meta=(EditCondition="BoolProperty"))
uint16 ConditionalInt;
UPROPERTY(meta=(BitMask, BitMaskEnum="EMyEnum"))
int32 BitFlags;
UPROPERTY(meta=(ClampMin="3", ClampMax="4"))
float myFloat;
```

#### 1.6 USTRUCT()

BlueprintType	Structs with this attribute can be used as type
	inside Blueprints. Make and Break nodes get
	automatically generated.
USTRUCT(Blueprint	tType)
struct MyStruct	{
//	
}	
2 Useful Con	sole commands
• Show Collision:	Show collision components in game.
	amera: Switch to a separate camera, which you d freely and shows some additional debug infos.

- ich you
- g infos. • HighResShot [number]: Makes a screen shot with [number] times
- a resolution the screenshot should have. • [CVar] ?: Add a ? after a CVar name and a description about the

your normal screen resolution. Instead of [number] you can provide

- DumpConsoleCommands: Prints a list of all available console commands and CVars.
- slomo [float]: Slow down or speed up the game. slomo 1.0 is default. slome 1.5 is faster than normal, slome 0.5 is slower.
- open [mapname]: Load and opens the map with the given name. 3.3
- help: Opens a page in browser which, lists all console commands and variables with a description. Searching and filter for specific commands is possible.

### Classes and Functions

# 3.1 Base Gameplay Classes

CVar will be shown.

- UObject: The base class, all classes, that should be used within C++ must extend. The name of child classes should start with U (e.g. UMyNewClass).
- **AActor:** Actor is the base class for all objects, that can be placed in a level. An Actor can has various Components. Child classes should start with A (e.g AMyNewActor).
- **APawn:** The base class, for all actors, that should be controlled by players or AI.
- ACharacter: Characters are Pawn, which has a mesh collision and movement logic. They represent physical characters in the game world and can use CharacterMovementComponent for walking, flying, jumping and swiming logic.
- UActorComponent: The base class for all actor components. Components defines some reusable behavior, that can be added
- USceneComponent: An Actor Component, which has a transform (position and rotation) and support for attachements.
- UPrimitiveComponent: A SceneComponent which can show some kind of geometry, usable for rendering and/or collision. Examples for this type are StaticMeshComponent, SkeletalMeshComponent, or the ShapeComponents.

# 3.2 Datastructures and Helpers

• TArray: The mostly used container in UE4. The objects in it have a well-defined order, and functions are provided to create, get, modify or sort the elements. Similar to C++'s std::vector. You can iterate over the element like this:

```
TArray<AActor> ActorArray;
//Add MyActor 3 times
ActorArray.Init(MyActor, 3);
ActorArray.Add(AnotherActor);
//Retrieve the first Actor from array
auto FirstActor = ActorArray[0]
//Iterate over all Actor in Array
for (AActor* Actor : ActorArray) {
    Actor->SomeFunc();
```

• **TMap:** A container, where every element has a key (of any type), via which you identify every element. Similar to std::map

```
TMap<int32, FString> StringMap;
StringMap.Add(4, TEXT("Foo"));
StringMap.Add(-1, TEXT("Bar"));
//Iterate over all Pairs
for (auto& pair : StringMap)
    pair.Key; //Gets the key of the pair
    *pair.Value; //Gets the value of pair
```

• TSet: A (fast) container to store unique elements without order. Similar to C++'s std::Set

```
TSet<int32> mySet;
mySet.Add(3); //mySet = [3]
mySet.Add(5); //mySet = [3,5]
mySet.Add(3); //mySet = [3,5]
//Only one 3 can be added to mySet
```

• TSubclassOf: When you define a UProperty with the type TSubclassOf<UMyObject>, the editor allows you only to select classes, 3.4 Assertions which are derived from UMyObject.

```
UPROPERTY(EditAnywhere)
TSubclassOf<AActor> ActorType;
```

- FName: FNames provide a fast possibility to reference to things via a name. FNames are case-insensitive and can not be manipulated (they are immutable)
- FText: FText represents a string that can be displayed to user. It has a built in system for localization (so FTexts can be translated) and are immutable.
- FString: FString is the only class that allows manipulation. FStrings can be searched modified and compared, but this makes FStrings less performant than FText or FName.

#### Useful Functions and snippets

• UE\_LOG(): This functions allows to print message to the UE Log or the Output Log in the Editor. You can set a category (you can use LogTemp for temporal usage) and verbosity (like Error, Warning or Display). If you want to output a variable, you can use printf syntax. Usage Example:

```
//Print Test to console
UE_LOG(LogTemp, Warning, TEXT("Test"));
//Print the value of int n and a string
UE_LOG(LogTemp, Display, TEXT("n=%d"), n);
UE_LOG(LogTemp, Error, TEXT("%s"), MyString);
```

• AddOnScreenDebugMessage(): If you want to print a debug message directly to the screen you can use AddOnScreenDebugMessage() from GEngine. You can specify a key, displaying time and display color. A message overrides an older message with the same key. Usage example:

```
GEngine->AddOnScreenDebugMessage(-1, 5.f,
     FColor::Red, TEXT("5 second Message"));
//Use FString, if you want to print vars
GEngine->AddOnScreenDebugMessage(-1, 5.f,
     FColor::Red,
     FString::Printf(TEXT("x: %f, y: %f"), x, y));
```

• NewObject(): NewObject() creates a new UObject with the specific type. Objects created using NewObject() are not visible to the Editor, if you need that, use CreateDefaultSubObject() instead. Usage example:

```
auto RT = NewObject<UTextureRenderTarget2D>();
```

• CreateDefaultSubobject(): This function creates a new named UObject with the specific type in the context of the current actor. Created objects are visible to the Editor, but this function can only be used in constructor. Usage example:

```
auto Mesh = CreateDefaultSubobject
    <UStaticMeshComponent>(FName("Mesh"));
```

• LoadObject(): This function loads an objects from a specific asset. Usage example:

```
auto Mesh = LoadObject<UStaticMesh>(nullptr,
    TEXT("StaticMesh', /Asset/Path/Mesh.Mesh', );
```

• Cast(): Casts an object to the given type. Returns nullptr if the object is not castable to this type. The object that should be casted, must be based on UObject, to work properly. Usage example:

```
AActor* Actor = Cast<AActor>(Other);
if(Actor != nullptr) {
/* do something */ }
```

• Console Variables: To define a variable that can be changed via editor (CVar), you can use TAutoConsoleVariable in any C++ file:

```
static TAutoConsoleVariable<int32> CVarMyVar(
TEXT("r.MyVar"),
2,//Default value
TEXT("CVar Description\n")
TEXT(" 1: Infos about possible values \n"),
ECVF_Scalability | ECVF_RenderThreadSafe);
```

The last parameter are some flags, that defines the behavior of the CVar. When you add ECVF\_Cheat flag, the CVar can be only changed in cheat mode. If you want to access the CVar's value in C++, then use this:

```
// only needed if you are not in the same cpp file
extern TAutoConsoleVariable<int32> CVarMyVar;
// Retrieve the MyVar value via Game Thread
int32 MyVar = CVarMyVar.GetValueOnGameThread();
```

Assertions can be used to ensure that specific conditions are fulfilled, before continue in the program flow. If the checks are not successful, the execution is halted. Assertions will only work when the DO\_CHECK macro is set (and not zero) during compiling. There are different types of assertions:

• check(): If the expression inside check() is false, the execution will be halted. The expression is only evaluated, when DO\_CHECK is set. If you need that the expression is always evaluated, then use verify().

```
check(OneProperty == 1);
verify(ImportantCall() != nullptr);
```

- **checkf()**: Behaves like check(), but additional debug info is printed. verifyf() works analogous.
- checkNoEntry(): You can mark code path that should never be executed with this assertion. If it is still be called, the execution is

```
switch(Property) {
   case EEnum: Val1:
       return 1;
   default:
       checkNoEntry();
```

• unimplemented(): Use this assertions, on functions that are yet unimplemented or must be overridden to work properly.

```
void Function() {
   //This func must be overriden to work
    unimplemented();
```

# 3.5 Draw Debug Functions

To use the following functions you need to include DrawDebugHelpers.h.

• DrawDebugPoint(): Draw a point in the world at a given location. You can choose Color and size of the point:

```
DrawDebugPoint(
  GetWorld(),
  MyLocation, //The location as FVector
  20, //size of the point
  FColor(255,0,0), //the color
  false, //Not persistant
  10.f //10s lifetime
```

• DrawDebugLine(): Draw a line between to points in the world:

```
DrawDebugLine(
  GetWorld(),
  Start, //Start point
  End, //End point
  FColor(0,255,0), //Line Color
  false, //Not persistant
  -1, //Infinite lifetime
  10 //Line Thickness
```
